

LPS: longest proper prefix of $S[0..i]$ that is a suffix of $S[0..i]$.

$LPS[0] = 0$ because a length 1 string has no proper prefix.

Prefix "A" = suffix "A" $\neq$ length 1

Prefix "AB" $\neq$ suffix "BA"

the only prefix is "A" which is not a suffix
 $LPS = [0, 0]$

$LPS = [0, 0, 1]$

$S = A \ B \ A \ B \ C \ A \ B \ A \ B$
0 1 2 3 4 5 6 7 8

$S = A \ B \ A \ B \ C \ A \ B \ A \ B$
0 1 2 3 4 5 6 7 8

Algorithm: two-Pointers

- R represents the end of the suffix we are currently evaluating.
- L represents the length of the matching prefix to the suffix ending at $R-1$.
→ because of 0-based indexing, it also represents the index of the next expected char for this prefix.

from prior iteration..
not the to-be-evaluated R index.

Invariants:

$$S[0..L-1] = S[(R-1)-(L-1)..R-1]$$

0 1 2 3 4
a b a b _
↑ ↑
L R
(currently evaluating)

$S[0..L-1]$

a b a b _

$$S[(4-1)-(2-1)..4-1] = S[2..3]$$

$$LPS[R-1] = L \text{ (length)}$$

if $S[L] = S[R]$ then this char matches the expected next prefix-suffix char.

↳ update invariant: $LPS[R] = L+1$

↳ prepare next iteration's evaluation: $L++$, $R++$

else: we cannot extend the current prefix.

if $L = 0$: $++R$

else: $L = LPS[L-1]$

$S = \underline{A \ B \ A} \ C \ \underline{A \ B \ A} \ B$
↑ ↑
L R (currently evaluating)

↳ since $S[L] \neq S[R]$, we can't extend the prefix.

↳ However, it's possible that a **smaller** suffix could still exist ending at R .

Since we only know that $S[L] \neq S[R]$, we can try to see if

the longest prefix-suffix ending before this character ($L-1$), is a valid prefix-suffix ending at R .

↳ $L = LPS[L-1]$

↳ $\underline{A \ B \ A} \ C \ A \ B \ A \ B \Rightarrow \underline{A \ B \ A} \ C \ A \ B \ \underline{A \ B}$ ✓
↑ ↑ old R for $L=1$

the next iteration will find this match, otherwise if $S[L] \neq S[R]$ again, we would perform the same operation until $L=0$.

* the base case is when $L=0$, and $S[L]$ still doesn't match $S[R]$, we simply increment R .
